

Assignment 3 – Human Computer Interaction

Step 1: URL of the poorly designed site: <https://whenisgood.net/>

Step 2: What's designed poorly?

First off, there's zero visual hierarchy. Everything kind of looks the same size and color, which makes it hard to know where to look or what to click. Nothing stands out or guides you.

Second, the layout feels messy and awkward. The text and buttons are all bunched up, and there's no real structure. It doesn't use space well—it just feels unbalanced and weird to scroll through.

Third, the colors and fonts make it look super old. There's a lot of low contrast text, and it's not very readable. The site just gives off "2000s web" energy instead of something modern and clean.

Step 3: Application & Method Used

I used Zed, my favorite code editor, and wrote all the HTML and CSS manually. I previewed the site locally in my browser by saving the file as .html and opening it with Chrome. I didn't use any frameworks or templates—just clean, custom code from scratch.

Step 4: Design Improvements Based on HCI Principles

First, I created a clear visual hierarchy. I made the title big, used bold subtitles, and added a strong call-to-action button so users instantly know what to do.

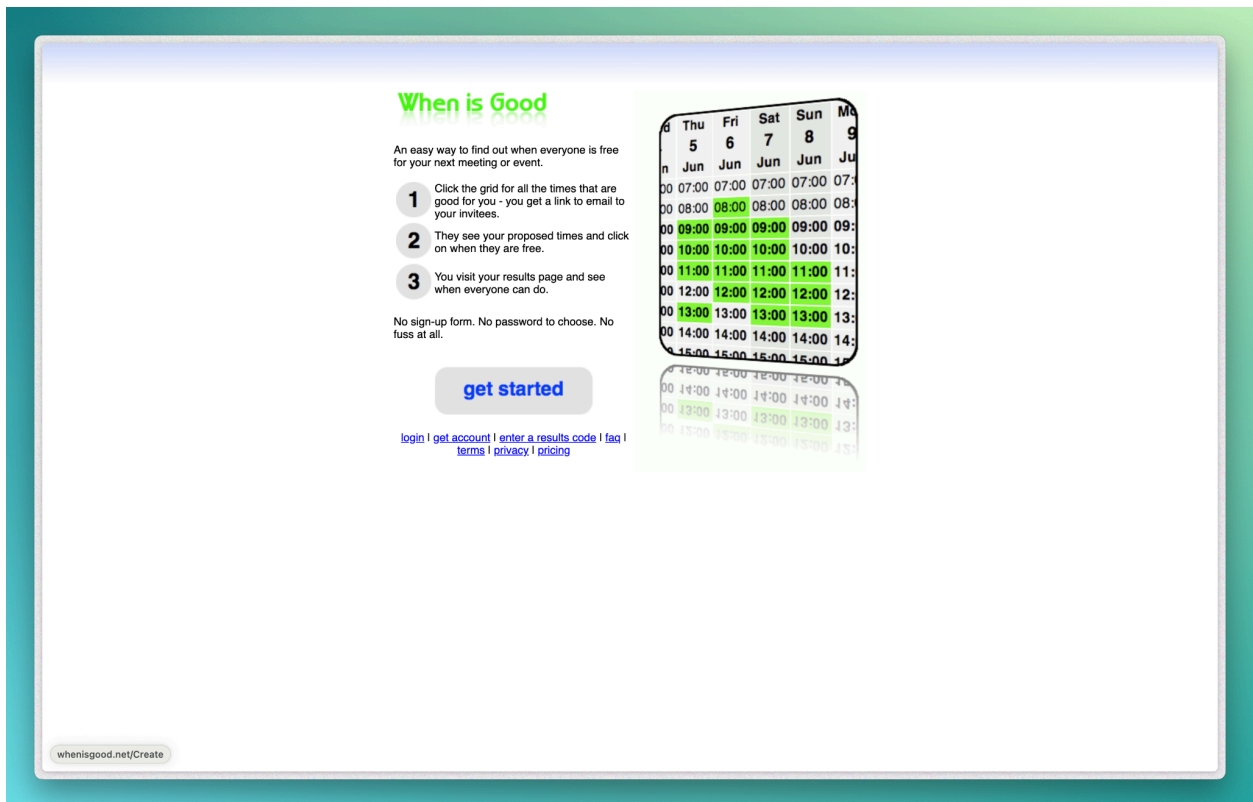

Second, I grouped related info together using proximity, like putting the three steps into a single section and spacing them evenly. This makes it easier to scan and understand.

Third, I used consistent alignment and white space so everything feels clean and organized. I also picked a soft blue and green color scheme to make it feel fresh and modern, instead of dull and outdated.

I also used responsive design to make sure it looks good on phones, which the original site doesn't really do. And I improved readability by picking better fonts, using more contrast, and making sure text isn't squished together.

Step 5: Before and After Screenshots

Before:

After:
